Present day science and technology have become increasingly based on studies and applications of thin films. This is especially true of solid state physics, semiconductor electronics, integrated optics, computer science and the like. In these fields it is necessary to use films with an ordered structure, especially single crystalline films, because physical phenomena and effects in such films are most reproducible. Also active parts of semiconductor and other devices and circuits are created as a rule in single crystal bodies. To date single crystalline films have been mainly epitaxial or heteroepitaxial, i.e. they have been grown on a single crystalline substrate and principal trends, e.g. in the evolution of integrated circuits (ICs) have been based on continuing reduction in feature size and increase in the number of components per chip. However, as the size decreases into the submicrometer range, technological and physical limitations in integrated electronics become more and more severe. It is generally believed that a feature size of about 0.1 μm will have a crucial character. In other words, the present two dimensional ICs are anticipated to reach their limit of minimization in the near future and it is realized that further increase of packing density and/or functions might depend on three dimensional integration. To solve the problem, techniques for preparation of single crystalline films on arbitrary including amorphous substrates are essential. **Wafer Level 3-D ICs**

Process Technology Chuan Seng Tan, Ronald J. Gutmann, L. Rafael Reif, 2009-06-29 Three dimensional 3D integration is clearly the simplest answer to most of the semiconductor industry's vexing problems: heterogeneous integration and reductions of power, form factor, delay and even cost. Conceptually, the power, latency and form factor of a system with a fixed number of transistors all scale roughly linearly with the diameter of the smallest sphere enclosing frequently interacting devices. This clearly provides the fundamental motivation behind 3D technologies which vertically stack several strata of device and interconnect layers with high vertical interconnectivity. In addition, the ability to vertically stack strata with divergent and even incompatible process flows provides for low cost and low parasitic integration of diverse technologies such as sensors, energy scavengers, nonvolatile memory, dense memory, fast memory, processors and RF layers. These capabilities coupled with today's trends of increasing levels of integrated functionality, lower power, smaller form factor, increasingly divergent process flows and functional diversification would seem to make 3D technologies a natural choice for most of the semiconductor industry. Since the concept of vertical integration of different strata has been around for over 20 years, why aren't vertically stacked strata endemic to the semiconductor industry? The simple answer to this question is that in the past the 3D advantages while interesting were not necessary due to the tremendous opportunities offered by geometric scaling. In addition, even when the global interconnect problem of high performance single core processors seemed insurmountable, without innovations such as 3D alternative architectural solutions such as multicores could effectively delay but not eliminate the need for 3D.
