Types of Heat Transfer

Temperature differences are not as we realize for the air conditions convection, and radiation.

Convection is heat transfer by the movement of the fluid. As air is heated, it expands and the air particles move apart, they make it rise. This is because they are taking up more space. As air rises and the cooler air sinks, a hot air balloon rises. This makes the air circulate. Convection also occurs in the ocean. Convection also occurs in the ground. Cooler water sinks.

Radiation is heat transfer by the form of electromagnetic waves. All objects emit thermal energy in the form of electromagnetic waves, causing the temperature to rise.

Particle Arrangement

To understand how heat moves, we need to know how particles are arranged. On Earth, all matter is made up of particles. These particles are constantly vibrating. The more energy they have, the faster they vibrate. This is why a hot object feels warmer than a cold object.

Figure 1: Solid

Thermal Equilibrium

Particles are always vibrating and this vibrating motion produces thermal energy. All matter is constantly vibrating, so all matter has some amount of thermal energy. Heat transfer is how thermal energy moves from one place to another. Lucky for us, it is easy to predict how heat moves. Thermal energy will always travel from warmer objects to cooler objects until the energy is equally distributed. When you have two objects that are at different temperatures, thermal energy moves from the warmer object to the cooler object until they are both at the same temperature. This is called thermal equilibrium. Once thermal equilibrium is established, the temperature of both objects will remain constant until you can think of a way to change it.
