Vestibular Evoked Myogenic Potential Vestibular Evoked Myogenic Potential:

Vestibular Evoked Myogenic Potential Toshihisa Murofushi, Kimitaka Kaga, 2009-03-28 The vestibular labyrinth consists of two compartments the lateral anterior and posterior semicircular canals the utricle and the saccule At the beginning of the twentieth century Robert Brannan proposed the caloric test as a clinical test of the lateral semicircular canal This test enabled clinicians to assess the individual lateral semicircular canal function easily by using the simple method of irrigating the external ear canal with cold or warm water and observing the induced nystagmus We believe that the caloric test was a breakthrough in the field of vestibular research However as far as the other compartments were concerned there was no simple clinical test equal to the caloric test for the lateral semicircular canal function At the end of the twentieth century the vestibular evoked myogenic potential VEMP test was proposed as a new method for assessing the individual saccule function This test has some unique attributes First it uses sound stimulation even though it is a test of the vestibular system This appears to be a contradiction neurophysiologically As a result in its early stages there were controversies concerning the origin of the responses However such controversies have been overcome by basic neurophysiological studies and clinical studies Above all sound sensitivity of the saccular afferents shown in cats and guinea pigs with single unit recording methods became the main supporting evidence Nowadays VEMP is one of the routine clinical tests for balance disorder

Fundamentals of Vestibular Evoked Myogenic Potentials Sujeet Kumar Sinha, Niraj Kumar Singh (Audiologist), Animesh Barman, 2022 Vestibular evoked myogenic potentials VEMPs are essential in assessing the otolith function in individuals with various vestibular disorders There are three types of vestibular evoked myogenic potentials cervical vestibular evoked myogenic potentials ocular vestibular evoked myogenic potentials and masseter vestibular evoked myogenic potentials are recorded in various clinical settings The book Fundamentals of Vestibular Evoked Myogenic Potentials covers all the information related to all three types of VEMPs The book has eighteen chapters containing information on recording factors affecting and applications of VEMPs in various vestibular pathologies such as Meniere's disease Labyrinthitis BPPV NIHL vestibular neuritis third window syndrome congenital sensorineural hearing loss ototoxicity vestibular Schwannoma and diseases of the central nervous system *Objective Detection of Vestibular Evoked Myogenic Potentials*, 2021 Cervical and ocular vestibular evoked myogenic potentials cVEMPs and oVEMPs respectively are considered objective tests of vestibular function measured using surface electromyography EMG In addition VEMPs are visually detected by an examiner often requiring a high level of stimulation to the ear to easily visualize a waveform plotted across time However a high level of stimulation like those used during routine VEMP testing is problematic since it has been shown to be unsafe in children when compared to adults Visual interpretation can also vary between examiners in cases of reduced vestibular function or when the level of required muscle contraction is low One method to alleviate the burden of visual detection is to use objective detection algorithms introduced as an alternative to visual detection of the auditory brainstem

response ABR An algorithm known as fixed single point Fsp estimates the signal to noise ratio SNR and statistically determines if a response is present Fsp has multiple clinical applications including a profound impact on the identification of hearing loss yet our understanding of how this algorithms behaves in VEMPs remains limited The purpose of this investigation was to characterize the behavior of Fsp in cVEMPs and oVEMPs and compare Fsp to visual detection in a group of young healthy participants Air conducted cVEMPs and oVEMPs were elicited using 500 Hz tonebursts For both responses the effect of stimulus level on Fsp was assessed For cVEMPs the additional effect of EMG activation was assessed by varying EMG targets between 10 150 V When applied to VEMP detection Fsp values increased as stimulus level increased in cVEMPs and oVEMPs however Fsp values remained significant at lower stimulus levels In cVEMPs Fsp values were comparable across different levels of EMG activation and maximum EMG activation did not yield larger Fsp values Finally Fsp was comparable to visual detection when detecting VEMP threshold These results showed the feasibility of Fsp when applied to VEMPs and have the potential to shift conventional thinking about the role of stimulus level and muscle contraction during routine VEMP testing
