American Book Publishing Record , 2007 **Stream Processor Architecture** Scott Rixner, 2001-10-31 Media processing applications such as three dimensional graphics video compression and image processing currently demand 10 100 billion operations per second of sustained computation Fortunately hundreds of arithmetic units can easily fit on a modestly sized 1cm² chip in modern VLSI The challenge is to provide these arithmetic units with enough data to enable them to meet the computation demands of media processing applications Conventional storage hierarchies which frequently include caches are unable to bridge the data bandwidth gap between modern DRAM and tens to hundreds of arithmetic units A data bandwidth hierarchy however can bridge this gap by scaling the provided bandwidth across the levels of the storage hierarchy The stream programming model enables media processing applications to exploit a data bandwidth hierarchy effectively Media processing applications can naturally be expressed as a sequence of computation kernels that operate on data streams This programming model exposes the locality and concurrency inherent in these applications and enables them to be mapped efficiently to the data bandwidth hierarchy Stream programs are able to utilize inexpensive local data

bandwidth when possible and consume expensive global data bandwidth only when necessary Stream Processor Architecture presents the architecture of the Imagine streaming media processor which delivers a peak performance of 20 billion floating point operations per second Imagine efficiently supports 48 arithmetic units with a three tiered data bandwidth hierarchy At the base of the hierarchy the streaming memory system employs memory access scheduling to maximize the sustained bandwidth of external DRAM At the center of the hierarchy the global stream register file enables streams of data to be recirculated directly from one computation kernel to the next without returning data to memory Finally local distributed register files that directly feed the arithmetic units enable temporary data to be stored locally so that it does not need to consume costly global register bandwidth The bandwidth hierarchy enables Imagine to achieve up to 96 of the performance of a stream processor with infinite bandwidth from memory and the global register file

Distributed Multimedia Palmer W. Agnew, Anne S. Kellerman, 1996 With global communications systems rapidly converging into a single interactive digital network the efficient effective and perhaps profitable conveyance of multimedia information to and from remote locations is now near at hand How is this convergence building who are the major players in it and how will your own future as an information user or provider be affected This book answers these questions Authors Agnew and Kellerman through their teaching and through their work with IBM s Multimedia Business Unit have been immersed for years in the development and direction of new information systems Drawing on their first hand experience they describe here for both technical and not so technical readers the technologies that are making distributed multimedia both possible and affordable They describe the principal applications and opportunities that have emerged from a combination of these technologies as well as the associated challenges yet to be met Through examples case studies and interviews with other experts they illustrate what is both technically feasible and economically viable what is likely to succeed and what well may fail The authors emphasis throughout this book is on where you fit in specifically what you can expect to see and gain from the emergence of distributed multimedia and how you can actively participate Whether your interest in the subject is business related or personal you will find here a broad perspective on the current state of the digital information industry and a valuable preparation for what s yet to come 0201765365B04062001
