

used—not by individuals, of course, but by the flow of the main stream of pedestrian over time. From these observations, a reasonable hypothesis can be constructed to explain what is observed and why the main was used in this way.

Combining various observations to the trends and rates and excluding them from handrails, markings on adjacent walls, and so on, typically, there are two main tension configurations. These result from stair ascent and descent. A third type is apparent where the tread configuration has been totally worn away as a result of the combined ascent and descent actions. All of these tension patterns occur naturally in response to the mechanical and frictional forces exerted by the motion of many shoes. The resultant damage reflects the way that the actions employed in ascent differ from those of descent.

All of the descriptions of movement and stair tension that follow describe conditions for normal stair use. The pattern for a monumental stair, a ship's companionway, or any other stair does not differ in principle, but the changed geometry changes the location and extent of the wear.

5.1.1 Tension of Ascent

In ascent, the lower leg swings forward and upward, placing the foot on the next tread. Then the foot is lowered onto the next-but-one tread. As normal climbing speeds and for the accepted range of tread-rise ratios, the foot is positioned so that none or all of its surface fits on the stair tread. This is a generalization; stair climbing is as individual an activity as walking, so the description aims to discuss the average motion that produces tension.

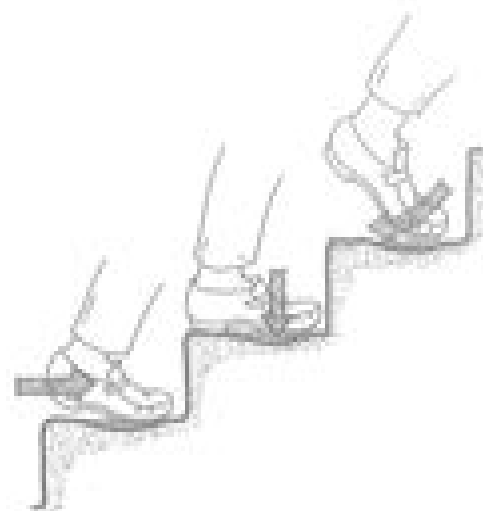

As ascent, the leading foot will obtain a degree of forward motion, which is

checked by the frictional connection between sole and foot (Fig. 5.2). Often both the heel and toe make contact with the nosel simultaneously, as most of the resultant frictional tension takes place in the central part of the tread, between the rising and the rise. The location of the tension is conditioned by the depth of the tread. The leg then tilts forward about the ankle. The body's weight shifts forward until the weight transfer onto the other foot on the next step up has been completed. While this is happening and the forward foot is lifting the body upward, the lower foot is pivoting forward onto the nosel (Fig. 5.2). It is exerting a backward thrust, which is resisted by the surface of the tread.

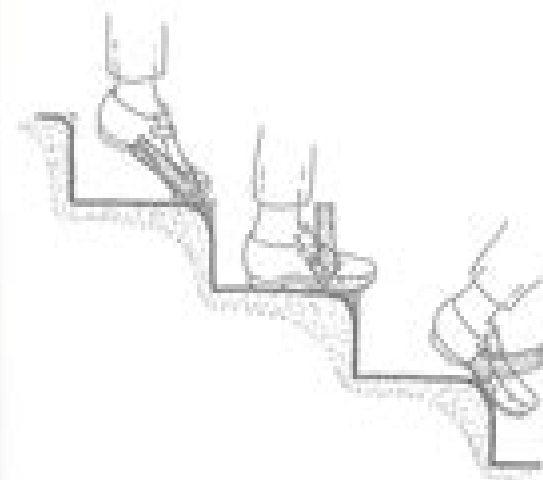

This time, tension is found on the tread in the area where the toes have been. This forms a tension tension pattern that tends toward that shown on the tread in figure 5.2. The actual position of the area of maximum wear due to ascent depends on the dimensions of the tread. It appears close to the nosing in the tread depth decreases.

5.1.2 Tension of Descent

Stair descent produces quite a different pattern. As the foot is lowered onto the next step, the toes are pointed down to some degree (Fig. 5.3). The foot reaches the step, usually two feet, and the body's weight is transferred to this forward leg. Depending on the tread rise and the speed of descent, the foot may overlap the nosing slightly, or may be positioned within the tread. In either event, the forward impetus of the foot is resisted by the frictional resistance of the front of the tread as the nosing. In due course, the other foot swings past, and it is set down on the next step. The body weight is transferred to it. The rear foot pivots on its toes as the trailing leg heels
